

German *Energiewende* – Different visions for a (nearly) climate neutral building sector in 2050

eccee summer study 2017

Panel 6: buildings policies, directives and programmes

30.05.2017

Dr. Veit Bürger, Öko-Institut e.V.

Agenda

1 Background and objectives of the study

2 Methodology and basic assumptions

3 Different visions how a nearly climate neutral building stock could look like in 2050

4 Conclusions and policy challenges

Background

- Study „Klimaneutraler Gebäudebestand 2050“, funded by the German Federal Environment Agency
- Main aim to investigate how the German building stock can be transformed into a “nearly climate-neutral” state by 2050
- In detail different visions/target states explored of how a nearly climate-neutral building stock could be realised in 2050
- Visions/target states parameterized as to reflect a rather broad corridor of visions in terms of two central dimensions
 - the reduction in final energy demand (efficiency) and
 - the composition of the fuel and technology mix (mainly the share of renewables)
- Important note: Analysis has been carried out before COP 21. Paris agreements imply even more mitigation efforts than presented here.

Methodology and basic assumptions

- Definition for nearly climate-neutral building stock
 - reduction of the non-renewable primary energy demand for the thermal conditioning of the building stock by 80% (compared to 2008)
 - the remaining, very low final energy demand, mainly supplied by renewable energy sources
- Indicators such as final and primary energy demand, CO₂-emissions and costs calculated based on stock model of the German building stock (residential and non-residential buildings)
- Eligible heating technologies: gas condensing boilers, wood/pellet condensing boilers, electric heat pumps, gas driven CHP, DH, +/- solar thermal, +/- ventilation/heat recovery, +/- onsite PV, absorption cooling)
- Three energy/renovation standards (non-renovated, fully renovated, fully renovated plus)
- Biomass restricted to 85 TWh; no imports of biomass, RES-E or PtX

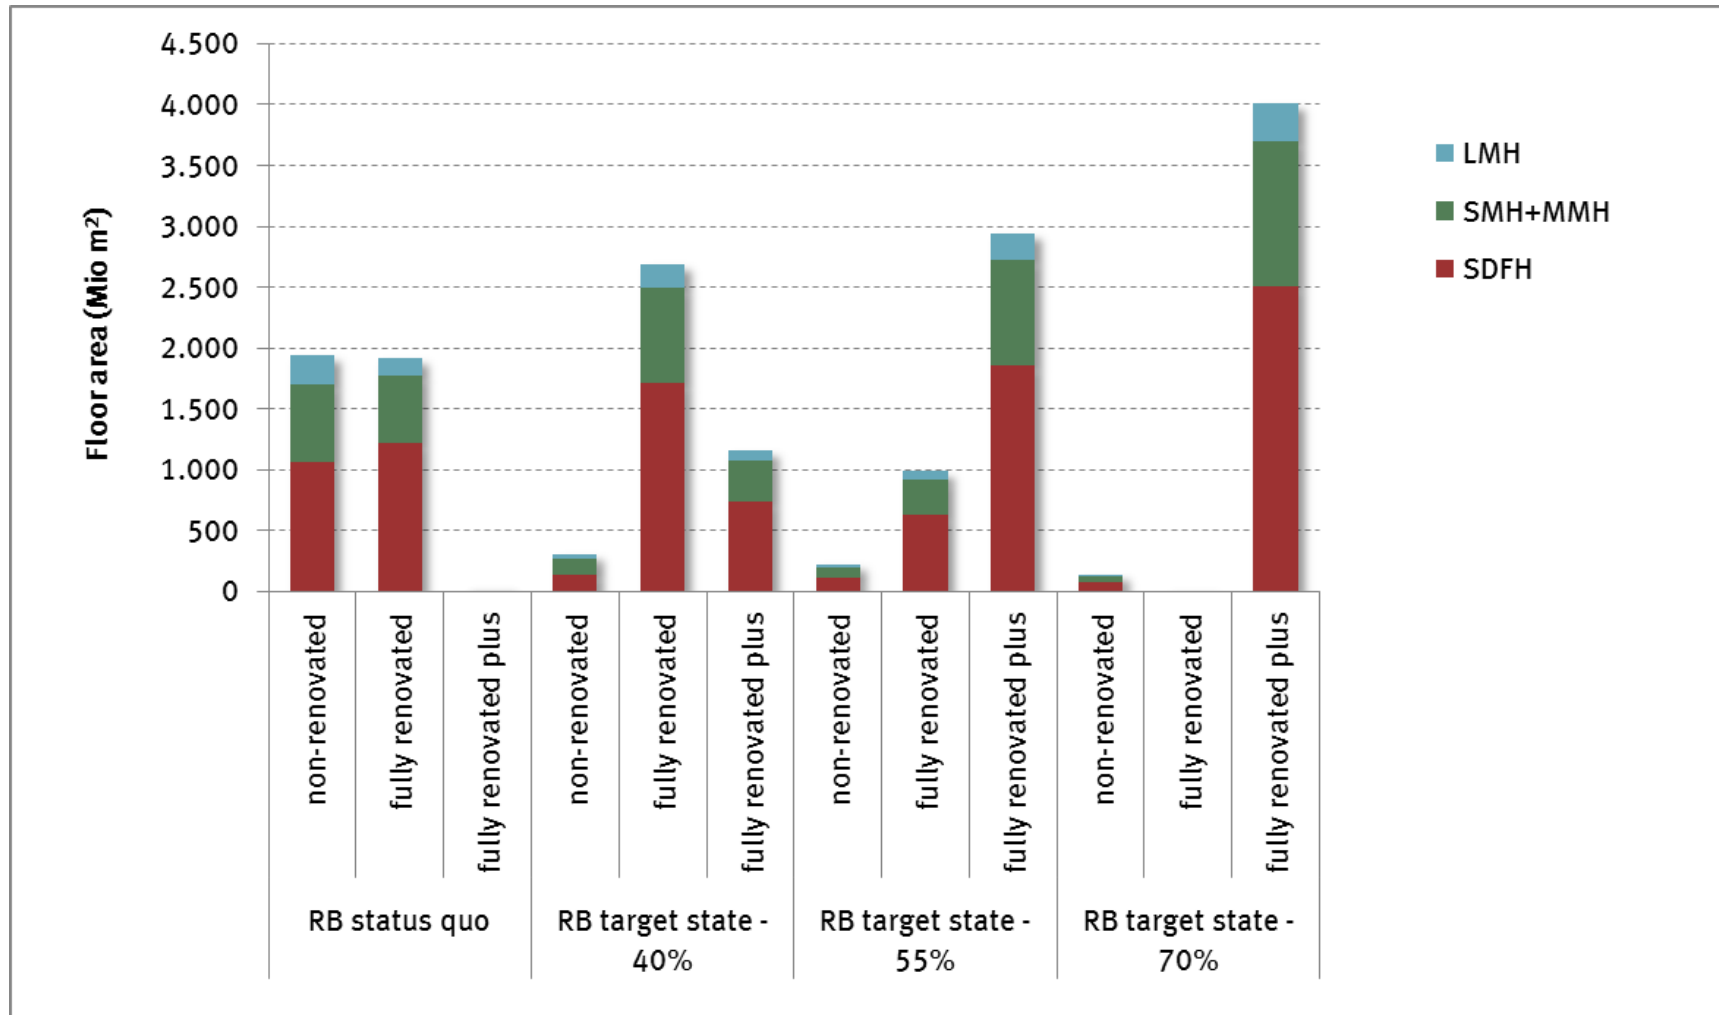

Key parameters characterising the two renovation standards

| | | Fully renovated | Fully renovated plus |
|-----------------------|-------------------|--|--|
| | | according to minimum standard from building code (EnEV 2014) for new buildings | according to the standard for passive houses |
| U-value external wall | $W/(m^2 \cdot K)$ | 0,29 | 0,10 |
| U-value roof | $W/(m^2 \cdot K)$ | 0,21 | 0,10 |
| U-value floor | $W/(m^2 \cdot K)$ | 0,37 | 0,20 |
| U-value window | $W/(m^2 \cdot K)$ | 1,37 | 0,70 |
| g-value window | $W/(m^2 \cdot K)$ | 0,63 | 0,45 |

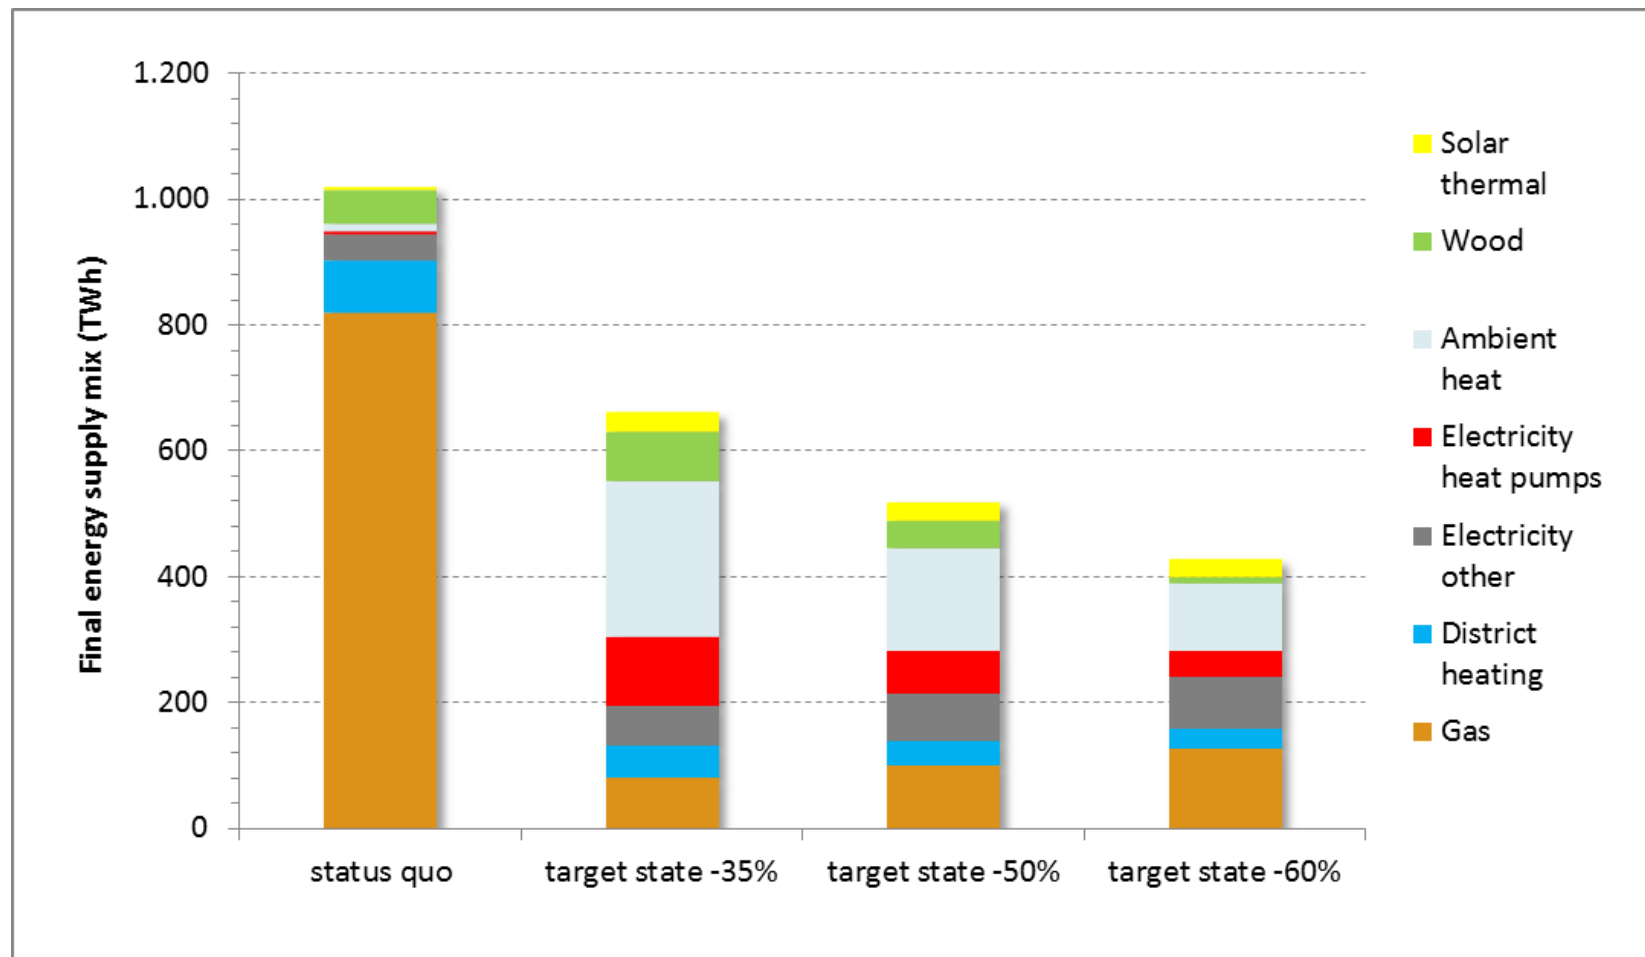

Definition of visions/target states

| | Residential buildings | | | Non-residential buildings | | |
|--|--|---------------------|---------------------|-----------------------------|---------------------|---------------------|
| Rate at which new buildings are being built | decreasing from 0,85% in 2015 to 0,2 % in 2050 | | | constant at 1,35 % annually | | |
| Rate at which buildings are taken out of use | constant at 0,3 % annually | | | constant at 1,35 % annually | | |
| Floor area development until 2050 | + 7 % | | | +/- 0 % | | |
| Visions/target states | Target state | Target state | Target state | Target state | Target state | Target state |
| | -70 % | -55 % | -40 % | -45 % | -35 % | -25 % |
| Reduction in final energy consumption until 2050 | -70 % | -55 % | -40 % | -45 % | -35 % | -25 % |

Floor area distribution of the different renovation standards in residential buildings

Final energy supply mix for the visions/three target states of the entire building sector

Annual costs 2050

^{*)} *Incidental costs* are costs that would occur anyway irrespective of whether a renovation is combined with an energetic modernization

Annual costs 2050

- Annual costs are slightly higher for the two visions/target states with higher energy efficiency saving ambitions than for the one with lower ambition
- However, costs difference is rather small (compared to the wide range of assumptions about learning curves for investments, energy price scenarios etc.)

Conclusions

- Due to renovation restrictions final energy demand can at the most be reduced by approx. 65%
- From a cost perspective analysis does not lead to a clearly preferable result of one of the visions/target states
- Other criteria become more relevant when deciding which vision/target state to be pursued, e.g.
 - acceptance regarding the various measures (roll-out of new RES incl. infrastructure vs profound renovation activities/thermal insulation)
 - challenges that arise from the increased roll-out of heat pumps, e.g. regarding the interaction with the electricity system
 - risk mitigation (cost implications if renovation measures were to be carried out beyond the typical reinvestment cycle, sensitivity to energy price increases)

Policy challenges

- Efforts to significantly increase the refurbishment rate over the coming decade
- Measures ensuring that the refurbishment market is capable to deliver the growing refurbishment volume at high quality
- Support framework aiming at a nearly zero-energy like standard to become the lead standard for renovations in the mid-term
- Strengthening incentives or regulatory requirements for gradually shifting the stock of conventional (fossil based) heating systems to RES + heat distribution systems towards lower temperatures
- Strengthening R&D efforts that aim at developing high-performance insulation materials and refurbishment concepts (e.g. industrial pre-fabrication of insulation elements)
- Development of an allocation strategy for biomass
- Improving data availability and monitoring schemes
